Overview

Introduced in Java 1.4, the `java.util.logging` package provides the classes and interfaces for performing applications logging. It allows applications running on the Java platform to log messages at various levels and allows the logged data to be exported to different types of destinations, including memory, output streams, consoles, files, and network sockets. The logging package also provides mechanisms for the logged data to be filtered and formatted. (i.e. XML, HTML)

Logging Levels

Minimizing the Impact of Logging

Logging a Method Call

Logging an Exception
